

CHAPTER 2

Growths, Wood Productions, Plant Succession, Plant Communities and Natural Regeneration in a Series of *Pinus kesiya* Plantations

Abstract

Studies on growths, wood productions, plant succession, plant communities and natural regeneration in 14-34 year-old pine plantations of 21 age classes were carried out at Boakaew Watershed Management Station, Chiang Mai province. Average growth increments of *Pinus kesiya* in these plantations were determined: height, 0.82 m/yr; diameter at breast height, 1.28 cm/yr; and tree volume, 6.23 m³/ha/yr. The number of succession broad-leaved tree species in plantations varied from 17 to 72 species with different densities of 540-2,688 trees/ha, and had volume increment of 2.63 m³/ha/yr. The density of pine trees varied between 75-429 trees/ha whereas other species had greatly different densities, 131-2,331 trees/ha. Shannon-Wiener indexes of species diversity in the plantations were varied from low to high values, varying 1.57-4.65. The succession broad-leaved tree species in pine plantations were mainly belong to the families of Fagaceae, Euphorbiaceae, Juglandaceae, Lauraceae, and Myrtaceae, etc. The natural succession results in development of plantation ecosyems to be a natural lower montane forest. However, it may need more many decades to develop the forest structure of successional pine plantations to be the lower montane forest.

2.1 Introduction

Uncontrolled timber harvesting and clearing of forests for agriculture in tropical regions, especially in highland watershed of northern Thailand caused the original forests occur as scattered patches of many small, intermediate and large fragmented forests. Deforestation and forest fragmentation contribute to the loss of biodiversity, decreases in valuable species and their productions. In the 1960s the Royal Forest Department promoted establishment of *Pinus kesiya* plantations and was covered extensively in northern Thailand, approximately 150,000 ha (RFD, 1993). At the present, mixed plantation of various tree species is used for reforestation in watershed areas, e.g. *Pinus kesiya*, *Prunus cerasoides*, *Ducynia indica* and *Betula alnoides*. However, *P. kesiya* is still the most common species for highland plantation because this pine is a pioneer tree species which grow vary fast, tolerate to harsh sites, low nutrient availability and grass competition (Harcharik and Kunkle, 1975). Furthermore, it has good survival, resistance to insects, disease and browsing by cattle (Bandaratillake, 1989).

All forest plantations have several management practices which lead to the high productivity per unit area. A carful pre-planting survey can help match species with site conditions for optimum growth and identify all land not suitable for planting. Only suitable species and suitable land need ever be planted to promote rapid growth. Growth rate and microclimate at establishment are influenced by soil properties and ground vegetation (Woods, 1976).

Forest plantations can facilitate forest succession in their understory through modification of physical, chemical and biological site conditions. Changes in light, temperature and moisture at the soil surface enable germination and growth of seeds transported to the site by wildlife and other vectors from adjacent forest remnants (Parrotta *et al.*, 1997). In Thailand, pine plantations usually have none or less succession in understory because silvicultural management in the past aimed to clear cut the deteriorate forests before planting and eliminated understory regeneration to promote the growth of the monospecific plantations.

Recently, plantation techniques have been changed by planting seedlings of many species including pine and broad-leaved species in the canopy gaps of deteriorated forest without forest clearing. At the present, many pine plantations have the natural succession of many broad-leaved tree species. Successful implementation of reforestation on highland watershed requires knowledge on growth dynamics in pine plantations including growths of pine, successional tree species, and their interactions. The purposes of this chapter are to evaluate pine growths, wood productions, plant succession, plant communities and natural regeneration in different aged of *Pinus kesiya* plantations as the useful informations for improving silvicultural practices in forest management.

2.2 Research Area

The research area was located in Boakaew Watershed Management Station, ($18^{\circ}45' - 21^{\circ}00'N$, $98^{\circ}25' - 98^{\circ}40'E$), Chiang Mai, Thailand, about 82 km north of Chiang Mai City. The altitude ranges between 1,200-1,600 m above mean sea level (Figure 2-1). The weather is rather cool all of a year. Mean monthly temperature is $20.9^{\circ}C$ with a maximum of $25.4^{\circ}C$ in April and minimum of $16.4^{\circ}C$ in December. Annual rainfall is 1,894 mm/yr. The prevailing forest type is lower montane forest and pine-montane forest, with dry dipterocarp forest on the dry mountain ridges and dry evergreen forest along the creeks.

Some activities about forest utilization of local people were observed such as selective felling of particular species; e.g. *Pinus kesiya* in order to collect cones for selling or burning the pine stem for stimulating resin, cutting some oak species (Fagaceae) for fire wood, etc.

The main cause of deforestation in Boakaew Watershed Management Station is forest clearing for agriculture and shifting cultivation particularly strawberry culture. Forest plantation in this area used the native fast-growing pioneer tree species especially *Pinus kesiya*, *Prunus cerasoides*, *Docynia indica* and *Betula alnoides* to recover degraded land during 1975-1995 covering area of 2,285 ha (Table 2-1). At the present, replanting of these tree species in the gaps of degraded forests over the watershed is done without forest clearing and monoculture plantation.

Table 2-1 Plantation areas of Boakaew Watershed Management Station

Year	Age (yrs)	Area (ha)	Species	Spacing (m ²)
1975	34	226	<i>Pinus kesiya</i>	4 x 4

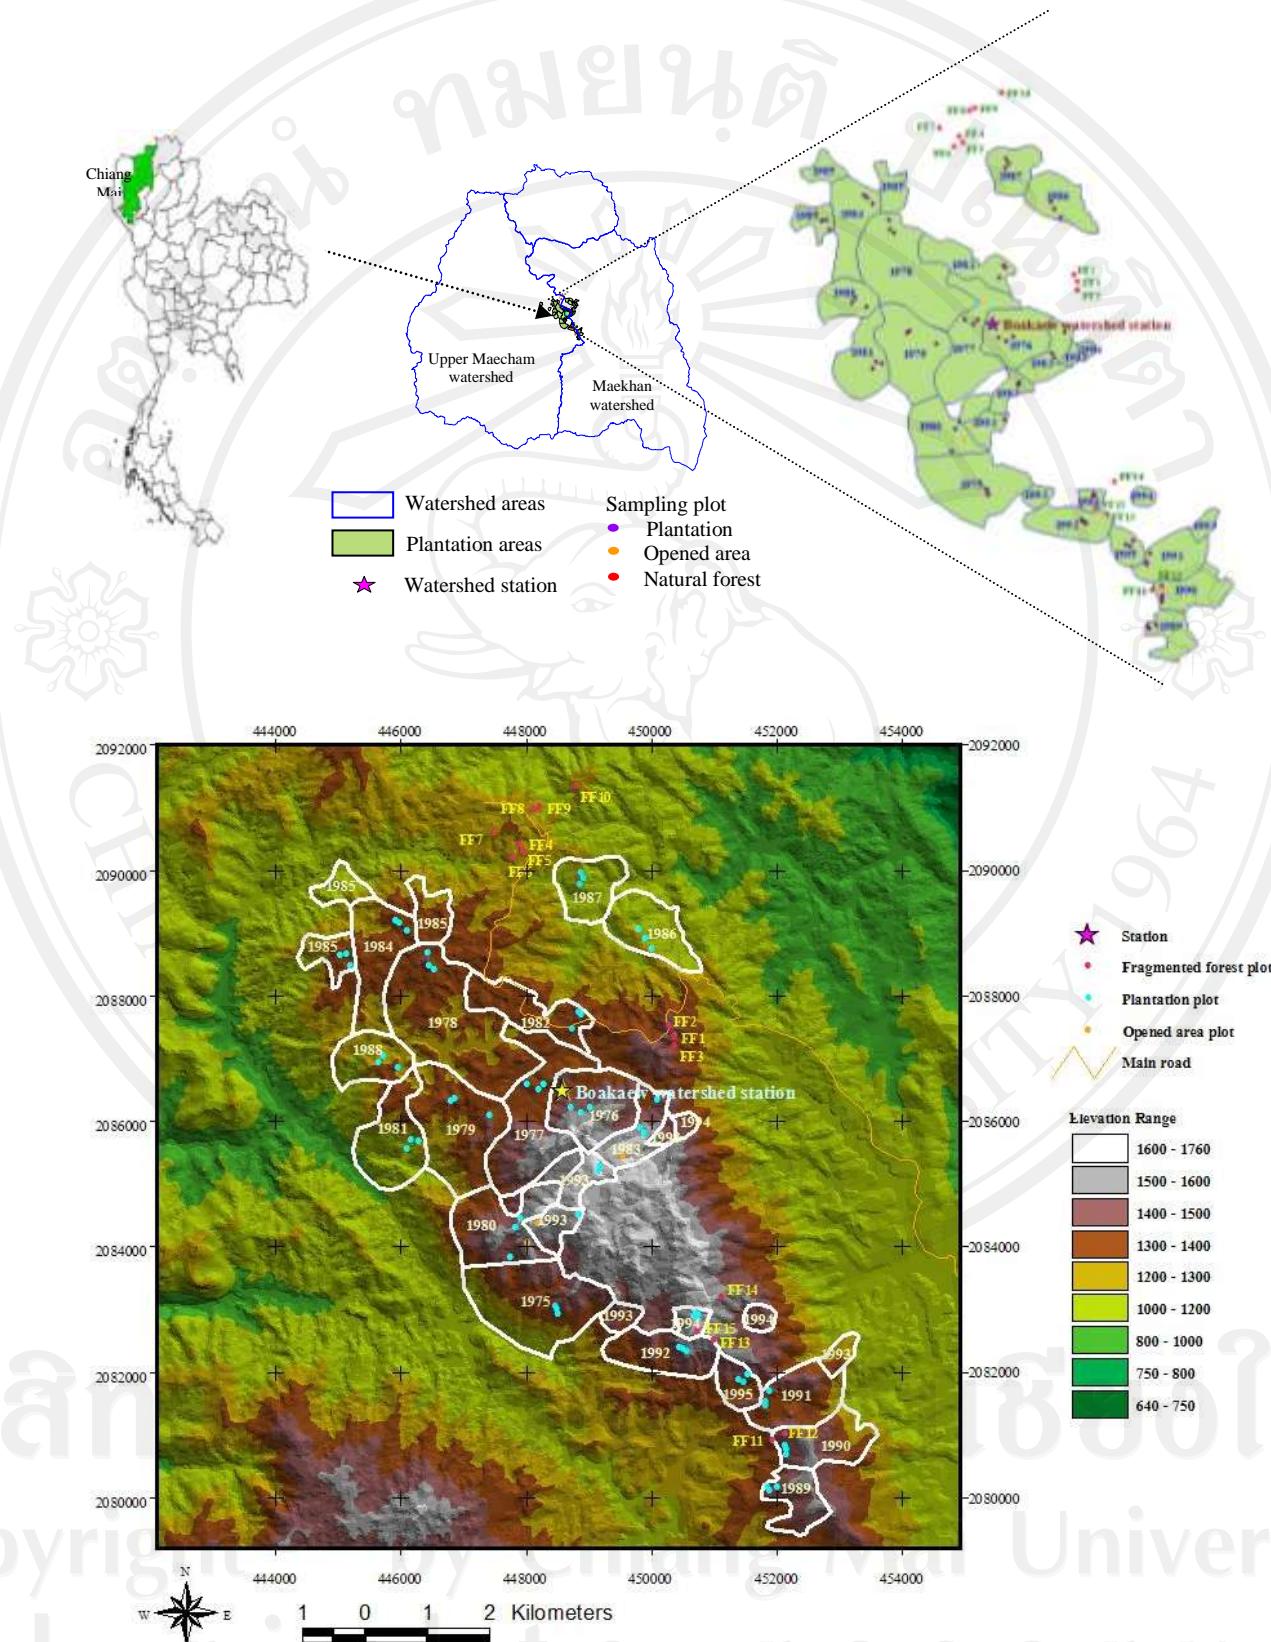

Figure 2-1 The location of study area

2.3 Materials and Methods

2.3.1 Vegetation Sampling

Sixty three sampling plots of $40 \times 40 \text{ m}^2$ in size were used to study growths and wood productions of *P. kesiya* plantations. Twenty-one age-class plantations including 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33 and 34 years old were chosen. Three plots (replications) were used for each age-class plantation. In each plot, stem girth at breast high (gbh) and tree height of pine and other trees were measured. Timber log was estimated for all trees having $\geq 30 \text{ cm}$ gbh. Timber grade was classified as A (straight stem), B (some curl stem), and C (very curl stem).

2.3.2 Physical Data of Sampling Plots

All plots were recorded for positions using GPS (Global Positioning System) at the center of plot, altitude, slope aspect and gradient. The slope gradient was measured every ten meters along the plot using abney.

2.3.3 Calculation of Tree Volume

The data of stem girth at breast high (gbh) and tree height of pine in a series of plantations were used for tree volume calculation. Five sample trees were cut in five age-class plantations from young to old plantations. The fallen trees were measured for tree volume according to a stratified-clip technique. Finally, the data collection was used to adjust allometric equation (Sahunalu, 1995).

Tree volume of other broad-leaved trees were calculated using equations of Sungpalee, *et al.* (2009)

$$\text{Where, } V = 0.00007629674(\text{DBH}^2 \cdot H)^{0.914502}$$

V	=	volume (cu.m.)
DBH	=	diameter at breast height (cm)
H	=	total height (m)

2.3.4 Plant Communities in a Series of Plantations

Species composition, richness and population density in a series of plantations are examined including frequency, density, dominance and important value index (IVI), similarity coefficient and species diversity index (Krebs, 1985). Two small sample plots of $5 \times 5 \text{ m}^2$ in size situated within $40 \times 40 \text{ m}^2$ were made for investigating natural regeneration and ground-covered species.

$$\text{Frequency} = \frac{\text{Number of occupied quadrats}}{\text{Number of all quadrats}} \times 100$$

$$\text{Density} = \frac{\text{Number of individuals of species } i}{\text{Number of all quadrats}} \text{ (trees/quadrat)}$$

$$\text{Relative frequency} = \frac{\text{Frequency of species } i}{\text{Sum of frequency of all species}} \times 100$$

$$\text{Relative density} = \frac{\text{Number of individuals of species } i}{\text{Number of individuals of all species}} \times 100$$

$$\text{Relative dominance} = \frac{\text{Stem basal area of species } i}{\text{Sum of stem basal area of all species}} \times 100$$

$$\text{IVI} = \text{Relative frequency} + \text{Relative density} + \text{Relative dominance}$$

$$\text{Relative IVI} = \frac{\text{IVI of species } i}{\text{Sum of IVI of all species}} \times 100$$

$$\text{Similarity} = [2w/(a+b)]100$$

Where, W = sum of the lowest value of IVI in both community a and b

a = sum of IVI in community a

b = sum of IVI in community b

Shannon-Wiener Index (SWI) of species diversity:

$$H = - \sum_{i=1}^S (p_i)(\log_2 p_i)$$

Where, H = index of species diversity

S = total number of species

p_i = proportion of individuals of species i to total individuals of all species

2.4 Results

2.4.1 Pine Growths and Wood Productions

(1) Pine Growths

Growths of *P. kesiya* in 14 to 34 year-old plantations of 21 age classes at Boakaew Watershed Management Station were analyzed in mean and increment of height and stem diameter (dbh) (Table 2-2). The mean height (H) and diameter at breast height were ranged from 15.31-23.30 m and 24.24-35.37 cm, respectively. The mean annual height increment was 0.82 m/yr (0.52-1.15 m/yr in range), and the mean annual dbh increment was 1.28 cm/yr (0.94-2.24 cm/yr in range).

Table 2-2 Growths of *Pinus kesiya* in a series of pine plantations of 21 age-class stands

Age (year)	Growth		Annual growth increment	
	H (m)	DBH (cm)	H (m/yr)	DBH (cm/yr)
14	16.13	31.35	1.15	2.24

Average	18.24	25.58	0.80	1.12
26	19.72	29.81	0.76	1.15
27	20.26	26.46	0.75	0.98
28	18.68	33.44	0.67	1.19
29	15.13	28.53	0.52	0.98
30	19.58	32.79	0.65	1.09
Average	18.67	30.21	0.67	1.08
31	21.49	35.37	0.69	1.14
32	20.46	32.32	0.64	1.01
33	23.30	34.52	0.71	1.05
34	21.47	32.10	0.63	0.94
Average	21.68	33.58	0.67	1.04
Mean	18.46	29.04	0.82	1.28

The growths of *P. kesiya* at Boakaew Watershed Management Station can be considered into 5 years period. The height and diameter increments of *P. kesiya* were 1.09 m/yr and 2.08 cm/yr for 14-15 year-old stands. The annual growth (height and dbh) increments of *P. kesiya* can be compared to other sites of northern Thailand, e.g. Mae Hard watershed station in early aged in 7-12 year-old were 1.54 m/yr and 2.63 cm/yr (Rojanakul, 1997); Doi Boa Luang Plantation in 12-37 year-old were 0.49 m/yr and 0.66 cm/yr (Khamyong, 2001); and Huey Bong experimental station in 14 year-old were 0.63 m/yr and 1.11 cm/yr (Wattanasuksakul *et al.*, 1996). FAO (1968) stated that height increment of *P. kesiya* in natural forests was 0.80 m/yr in 10-15 year-old, increasing to 1.0 m/yr in 15-20 year-old and up to 1.17 m/yr between 20-25 year-old; whereas dbh increment in early fifteen years was 0.94 cm/yr, increasing to 1.06 cm/yr in 15-20 year-old but reducing to 0.82 cm/yr in 20-25 year-old.

The relation between tree height and stem diameter showed in logarithm curve (Figure 2-2) was approximated by the relation,

$$\text{H} = 6.4383 \ln(\text{DBH}) - 2.9101 \quad (R^2 = 0.448)$$

Where, H = total height (m)
DBH = diameter at breast height (cm)

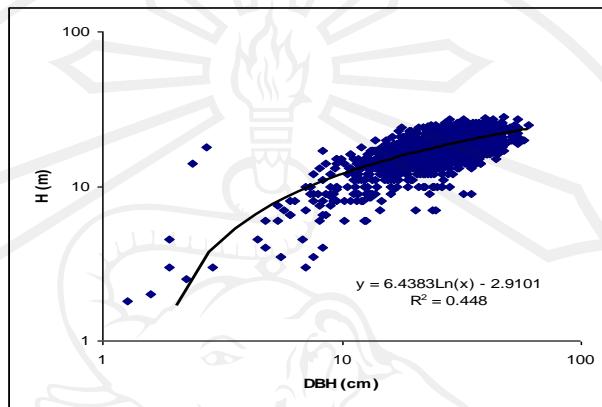

Figure 2-2 The relation between tree height and dbh of *Pinus kesiya* in pine plantations

(2) Wood Productions

Yield of *P. kesiya* was calculated from a volume equation derived from the exact volumes of five felling trees from five age-class plantations which were increased in normal growth without site effects. They included 17, 20, 26, 30 and 33 year-old stands. Volume regression model was applied from allometric correlation method by using power equation (Figure 2-3).

$$V = 0.00002 (D^2 H)^{1.0514} \quad (R^2 = 0.9783)$$

Where, V = stem volume over bark (m^3)
H = total height (m)
D = diameter at breast height (cm)

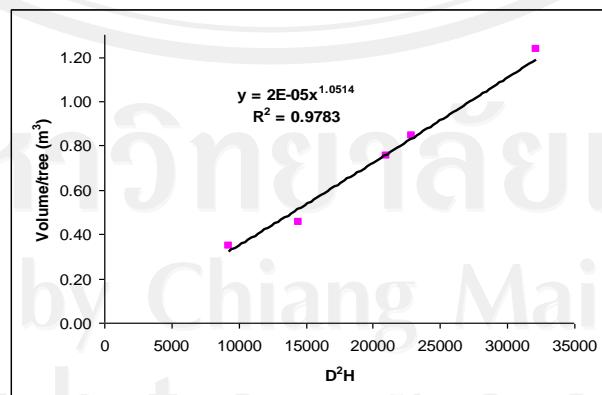

Figure 2-3 The relation between tree volume and the product of the square of dbh (D^2) and tree height (H) of *Pinus kesiya* by using a power equation

Five representative trees from five age-class plantations were measured individually for their dimensions in order to make growth regression models of 21 age-class stands (Figure 2-4).

$$\begin{aligned} H &= 14.016 \ln(x) - 24.461 & (R^2 = 0.8010) \\ DBH &= 14.046 \ln(x) - 14.357 & (R^2 = 0.9385) \\ V &= 1.1834 \ln(x) - 3.0149 & (R^2 = 0.9035) \end{aligned}$$

Where,

- V = stem volume over bark (m^3)
- H = total height (m)
- DBH = diameter at breast height (cm)
- x = age (year)

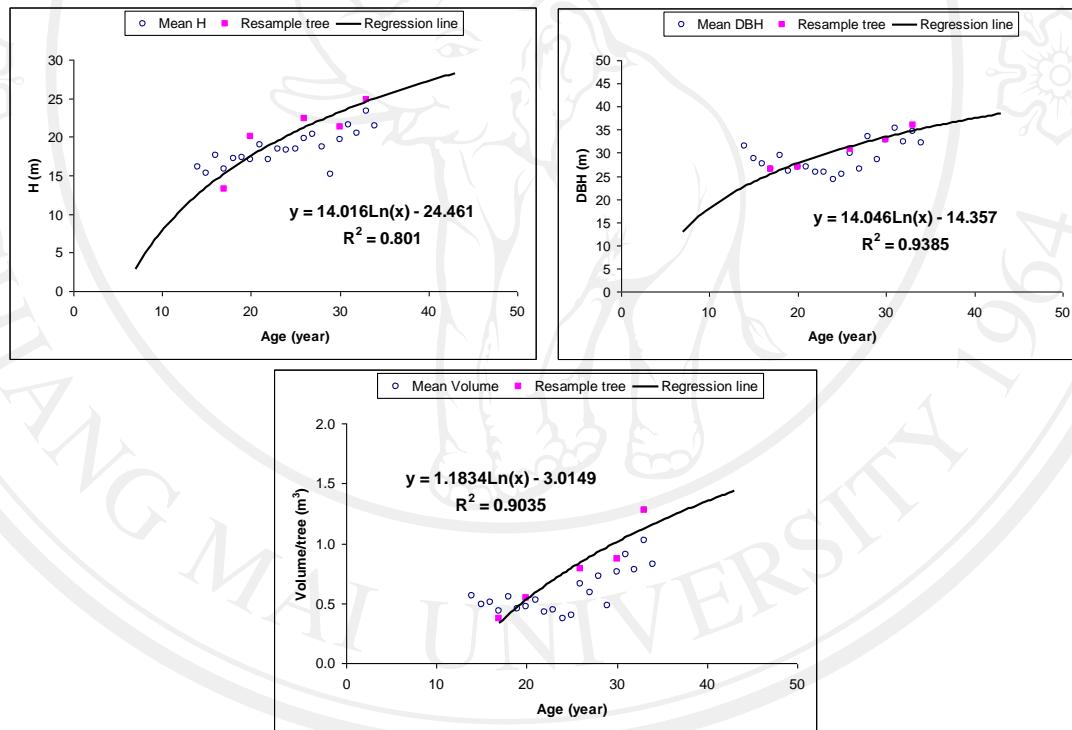

Figure 2-4 Growth models of tree height, dbh and stem volume of *Pinus kesiya* of 21 age-class stands

Stem volume of *P. kesiya* was estimated every age class of plantations by using constructed equation. The total volume of *P. kesiya* in a series of pine plantation were range from 32.73-337.10 m^3/ha , and the timber volume of *P. kesiya* were range from 19.93-200.62 m^3/ha . The results on growth and yield indicated by the mean of annual total volume increment (MAI) of *P. kesiya* was 6.23 $m^3/ha/yr$ (2.04-10.22 $m^3/ha/yr$ in range). The mean of annual timber volume increment of *P. kesiya* was 4.24 $m^3/ha/yr$ (1.17-7.21 $m^3/ha/yr$ in range) (Table 2-3). The highest annual total

volume increment of *P. kesiya* was $7.68 \text{ m}^3/\text{ha}/\text{yr}$ for 16 to 20 year-old stands which are considered as the juvenile stage.

Table 2-3 Wood productions of *Pinus kesiya* in a series of plantations of 21 age-class stands

Age (year)	Volume		Annual volume increment	
	$V_{\text{Total}} (\text{m}^3/\text{ha})$	$V_{\text{Timber}} (\text{m}^3/\text{ha})$	$V_{\text{Total}} (\text{m}^3/\text{ha}/\text{yr})$	$V_{\text{Timber}} (\text{m}^3/\text{ha}/\text{yr})$

Mean	148.64	100.97	6.23	4.24

Stem volume increment of *P. kesiya* at Boakaew Watershed Management Station was higher than Boa Luang Plantation which was reported as $3.44 \text{ m}^3/\text{ha}/\text{yr}$ (Khamyong, 2001). Yield increment of general *P. kesiya* plantations were in range of $3\text{-}4 \text{ m}^3/\text{ha}/\text{yr}$, whereas the intensive management could increase stem volume to $6\text{-}9 \text{ m}^3/\text{ha}/\text{yr}$ (Pousujja, 1984).

The yield and yield increments of *P. kesiya* in 21 age-class plantations were not increased with stand ages as their growths (Figure 2-5).

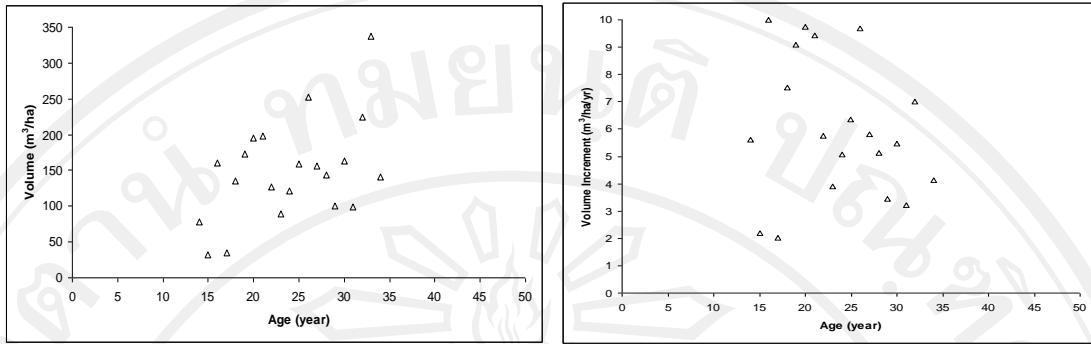

Figure 2-5 Mean volumes and volume increments of *Pinus kesiya* of 21 age-class stands

Timber volume of *P. kesiya* in a series of pine plantations can be classified with different stem-girth classes presented in Table 2-4. Most of *P. kesiya* were large trees which had stem girth in range of 50-150 cm.

Table 2-4 Timber volumes of *Pinus kesiya* with different timber quality and stem-girth classes in 21 age-class plantations

2.4.2 Plant Succession

(1) Growth of Succession Trees in a Series of Plantations

The mean height and stem dbh of succession trees ranged between 11.56-17.50 m and 14.67-27.33 cm, respectively. Their annual height and dbh increment were in range of 0.37-0.88 m/yr and 0.66-1.58 cm/yr (Table 2-5).

Table 2-5 Growths of succession trees in a series of plantations of 21 age-class stands

Age (year)	Growth		Annual growth increment	
	H (m)	DBH (cm)	H (m/yr)	DBH (cm/yr)

Average	14.73	24.33	0.45	0.75
Mean	13.74	21.25	0.61	0.94

The average growths (height and dbh) of *P. kesiya* and other broad-leaved trees in 21 age-class plantations were characterized according to real site conditions and real stand structures under natural succession. Site condition is the most important factor for determining productivity and profit. Figure 2-6 compared the mean height and dbh between *Pinus kesiya* and other broad-leaved trees over stand ages, and

Figure 2-7 showed the trend and equations of the mean height and dbh increments of *Pinus kesiya* and other broad-leaved trees in 21 age-class stands.

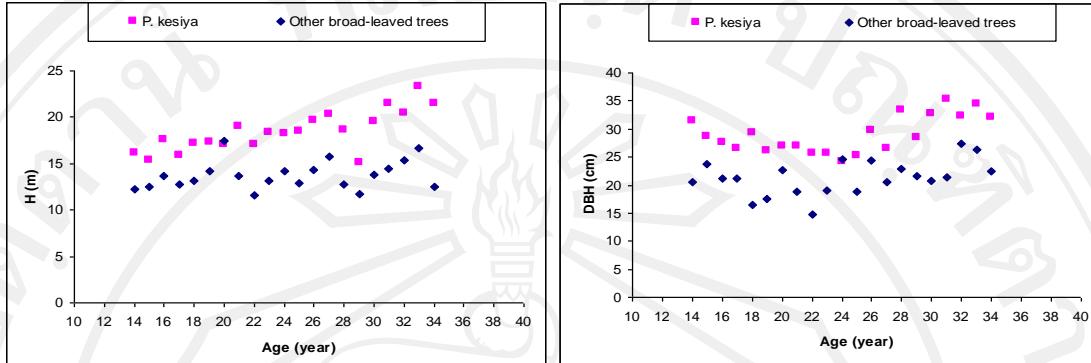

Figure 2-6 Mean height and dbh of *Pinus kesiya* and other broad-leaved trees in 21 age-class plantations

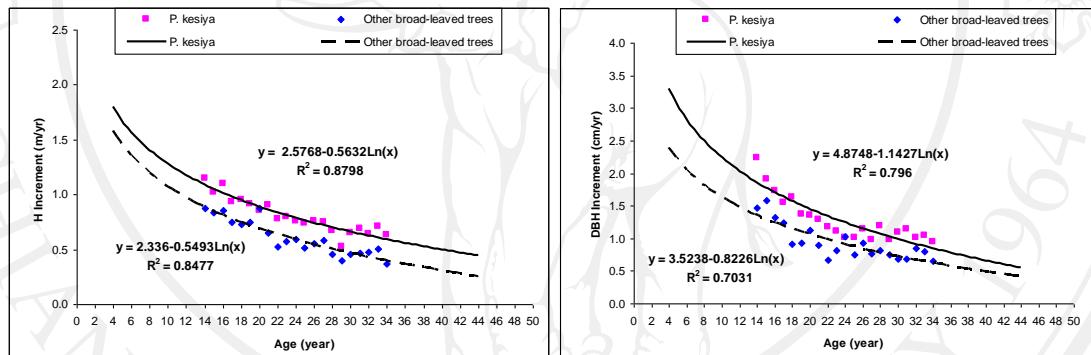

Figure 2-7 Mean height and dbh increments of *Pinus kesiya* and other broad-leaved trees in 21 age-class plantations

(2) Wood Production of Succession Trees in a Series of Plantations

Stem volumes of succession broad-leaved trees were estimated every age-class plantation by using equation of Sungpalee, *et al.* (2009). Their total volumes in a series of pine plantations were in range of 7.52-124.73 m³/ha, and the timber log volume were 4.16-67.30 m³/ha. The annual total volume increment of succession trees were varied between 0.23-4.43 m³/ha/yr, whereas the timber log volume increments were 0.13-2.23 m³/ha/yr (Table 2-6).

Figure 2-8 Over view of pine plantations at Boakaew Watershed Management Station

2.4.3 Plant Communities in a Series of Plantations

Plant succession in pine plantations resulted in changes of plant communities in different age stands. Some pine trees may die by the damage of disease, forest fire and competition (Oberhauser, 1997; Armitage and Wood 1980). Some may be cut for wood and non-wood products and provided gaps in plantations. Variations in species richness and composition were occurred in different age stands.

Table 2-8 presents the data of species richness and plant composition in 14 to 34 year-old pine plantations of 21 age-class stands. The number of succession tree species was different among 21 age-class pine stands, 17 to 72 species. Tree densities of these plantations were varied between 540-2,688 trees/ha separated to be 75-429 trees/ha of *P. kesiya* and 131-2,331 trees/ha of broad-leaved species. The importance value index (IVI) of *P. kesiya* in plantations varied from 10.65 to 60.09% whereas the Shannon-Wiener indexes (SWI) were 1.57 to 4.65 (Table 2-9).

The data of height class and stem girth at breast height (gbh) class distribution were shown in Table 2-10 and Table 2-11. Most of *P. kesiya* were large trees with 15 to 20 m in height and gbh of 50 to 150 cm, whereas succession broad-leaved species were mainly small trees with 5 to 10 m in height and gbh of less than 50 cm (Figure 2-10). These included tree species in the families of Fagaceae, e.g. *Castanopsis diversifolia*, *C. acuminatissima*, *C. purpurea*, *Quercus brandisiana*, *Q. vestita*, etc. Other species were *S. wallichii*, *Ternstroemia gymnanthera*, *Anneslea fragrans* and *Elaeocarpus sphaericus*, etc. The succession broad-leaved species in pine plantations were almost same species existed in natural adjacent montane forests. Mother trees in plantations as well as adjacent forests have the potential role as sources of seeds/fruits in pine plantations. The natural succession in these plantations increases biodiversity enrichment, and thus the plantations can develop to be the climax montane forest. However, the seed dispersal was depended upon distance from the nearest seed source and altitude gradient (Geldenhuys, 1997; Khamyong *et al.*, 2004). Therefore, great differences of plant communities in different age pine plantations were observed, and the similarity values of plant communities among the plantations were varied in a wide range, 2-78%.

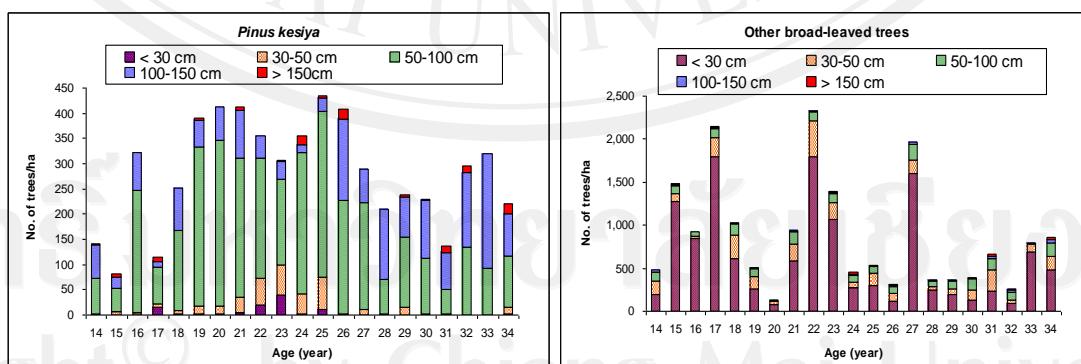

Figure 2-10 Tree densities of *Pinus kesiya* and succession broad-leaved trees with different stem-girth classes in 21 age-class plantations

2.4.4 Natural Regeneration and Ground-covered Species

Using 126, 5 x 5 m² sampling plots, the total number of seedling and ground-covered species existed in 21 age-class pine plantations were varied between 21-59 species (Table 2-12). The average densities of seedling and ground-covered species varied with a wide range among pine plantations, 15,267 to 72,567 individuals/ha. The densities of *P. kesiya* were greatly varied, 0-4,867 individuals/ha and other seedlings varied between 3,200-17,800 individuals/ha, whereas the ground-covered species were 3,200-65,033 individuals/ha. The common ground-covered species included *Ageratina adenophora*, *Chromolaena odoratum*, *Rubus rugosus*, *Hypolepis punctata*, *Adiantum capillus-veneris* and *Asparagus filicinus*. Most seedlings of woody tree species were *P. kesiya*, *Melastoma sanguineum*, *Leea guineensis*, *Glochidion acuminatum*, *Aporosa villosa*, *Wendlandia tinctoria*, *Schima wallichii*, *Engelhardtia spicata*, *Quercus vestita* and *Castanopsis purpurea*, etc. The limiting factors of plant succession were mainly fire disturbance, low light intensity and the presence of mature mother trees (Kianmaa, 2005).

Figure 2-11 Natural regeneration in *Pinus kesiya* plantations

2.5 Discussion

It was found that pine growths in a series of *P. kesiya* plantations were not increased with stand ages because of great variations of site factors and other causes. The plantation areas covered area of 2,285 ha with different altitude, 1,202-1,655 m msl. The growths were fast in 14-15 year-old stands and slow for 21 to 25 year-old. The 14-15 year-old plantations were located on mesic sites in lower areas whereas those stands of 21 to 25 year-old were xeric sites on the higher altitude. Thus, site moisture condition is one important limiting factor on pine growth. The forest fire occurred in some stands particularly on xeric sites might cause killing some pine individuals and resulted in lower tree density. The difference in pine densities among these plantations is considered as another important factor.

Annual volume increment of poor-site 21-25 year-old pine plantations in this study area was 5.48 m³/ha/yr. It was higher than plantations in the area of pine-dry dipterocarp forest at Boa Luang Plantation (3.44 m³/ha/yr)(Khamyong, 2001). The pine plantations in this area is located in area of pine-montane forest which has more cool weather and site moisture which are favorable for pine growth. Pine plantation in highland watershed areas of pine-dry dipterocarp and pine-montane forests can results in different pine growths. The pine-dry dipterocarp forest normally has very poor soil, lower moisture condition and annual forest fire whereas more fertile soil, higher moisture condition and occasionally fire is characteristics of pine-montane forest.

Plant succession affects on pine growth in older stands through competition and may results in standing dead of some individuals as the succession trees grow up to have the higher height and canopy. Another important factor is human disturbance through selective cutting of pine and burning the plantation forests during their clearing the forest nearby plantations for agriculture. However, the real growths and yields of pine in five different age class plantations, from young to older stands, maybe used to predict the functions which are represented the volume regression model of pine.

The natural regeneration was occurred in every age-class of plantations. The pioneer species show their highest levels of germination in large gaps and seedlings may grow very rapidly in full light (Raich and Gong, 1990; Kennedy and Swaine, 1992) whereas the climax species do not germinate or establish well in the large gaps (Howe *et al.*, 1985; Tomboc and Basada, 1978; Turner, 1990), and are poorly dispersed (Burgess, 1970). Seed dispersal in the natural habitat of *P. kesiya* is very effective, especially if seed trees are situated on near the ridge and upper slopes (Colling, 1967). Differences of species composition, richness and tree growths indicate to the successional stages and development to be montane forest. It may needs many decades or hundred years to change their species composition, richness and vertical-horizontal structures to the montane forest. The morphology of fruits and seeds of trees remained in plantations and adjacent forests affects on their spatial distribution and species composition. The variation of species composition in pine plantations was observed. The pioneer species existed densely in disturbed plantations such as *Wendlandia tinctoria*, *Glochidion sphaerogynum*, *G. acuminatum* and *Tristania rufescens*. The succession tree species were mainly in the families of Fagaceae, Euphorbiaceae, Juglandaceae, Lauraceae, and Myrtaceae which are almost the climax species in pine-montane forest.
